Abstract

This paper introduces Decentralized Collaborative Recursive Optimization (DECOR), an efficient stochastic algorithm for decentralized nonconvex-strongly-concave minimax optimization. Involving multiple agents, DECOR leverages gradient tracking and variance reduction techniques to achieve optimal complexity in both online and offline settings. The algorithm efficiently addresses constrained and unconstrained minimax problems, ensuring a linear speed-up in stochastic first-order oracle (SFO) complexity with respect to the number of agents. We provide a comprehensive convergence analysis, demonstrating that DECOR significantly outperforms existing decentralized methods in both computation and communication complexities.

Keywords: Decentralized Optimization; Nonconvex-Strongly-Concave Minimax; Stochastic Gradient Descent-Ascent (SGDA); Variance Reduction; Communication Complexity

1 Introduction

Decentralized optimization has emerged as a critical area of study due to its applicability in large-scale machine learning tasks, where the objective is to collaboratively optimize a global function across a network of agents. Unlike centralized methods that rely on a central server to aggregate information, decentralized approaches avoid communication bottlenecks by restricting interactions to neighboring agents, making them scalable and communication-efficient.

In recent years, minimax optimization problems, particularly those that are nonconvex in the primal variable and strongly concave in the dual variable, have garnered significant attention. These problems appear in a variety of machine learning applications, such as adversarial training, distributional robust optimization, and reinforcement learning. The complexity of solving such problems increases in decentralized settings due to the challenges of limited communication, stochastic gradient estimation, and variance reduction.

Despite notable progress in decentralized optimization for minimization problems, understanding the complexity of first-order methods for decentralized nonconvex-strongly-concave minimax problems remains limited. Existing algorithms either suffer from suboptimal convergence rates or fail to address the computational challenges posed by large networks and constrained optimization domains. This paper aims to address these gaps by proposing a novel decentralized method that achieves state-of-the-art complexity guarantees.

We introduce Decentralized Collaborative Recursive Optimization (DECOR), a unified framework for decentralized nonconvex-strongly-concave minimax optimization. DECOR integrates recursive gradient estimation and gradient tracking to overcome the limitations of existing methods. By leveraging variance reduction techniques, DECOR provides optimal convergence guarantees in both online (stochastic) and offline (finite-sum) settings, while maintaining communication efficiency across the network.

Formulations. Consider the decentralized minimax optimization problem, where m agents in a network collaborate to solve the problem

$$\min_{x\in\mathbb{R}^{d_x}} \max_{y\in\mathcal{Y}} f(x,y) \triangleq \frac{1}{m}\sum_{i=1}^{m} f_i(x,y) \tag{1}$$

We suppose that $f(x,y)$ is μ-strongly-concave in y; $\mathcal{Y} \subseteq \mathbb{R}^{d_y}$ is closed and convex; each local function on the i-th agent has the following stochastic form

$$f_i(x,y) \triangleq \mathbb{E}[F_i(x,y;\xi_i)]; \tag{2}$$

and the stochastic component $F_i(x,y;\xi_i)$ indexed by the random variable ξ_i is L-average smooth. The nonconvex-strongly-concave minimax problem (1) plays an important role in many machine learning applications, such as adversarial training [NK17, FO21], distributional robust optimization [SND18, LCDS20, JZWW21], AUC maximization [GYYY23, LYYY19, YGX$^+$21], reinforcement learning [QYW$^+$20, ZYB19, WYWH18, JS20], learning with non-decomposable loss [FLYH17, RLLY21] and so on. Following existing non-asymptotic analysis for nonconvex-strongly-concave minimax optimization problems [LJJ20b, LYHZ20, LJJ20a], we focus on the task of finding an ϵ-stationary point of the primal function $P(x) \triangleq \max_{y\in\mathcal{Y}} f(x,y)$.

In this paper, we also consider a popular special case of problem (1) when each random variable ξ_i is finitely sampled from $\{\xi_{i,1},\ldots,\xi_{i,n}\}$. That is, we can write the local function as

$$f_i(x,y) \triangleq \frac{1}{n}\sum_{j=1}^{n} F_{ij}(x,y) \tag{3}$$

We refer to the general form (2) as the online (stochastic) case and refer to the special case (3) as the offline (finite-sum) case. We define $N = mn$ as the total number of individual functions for the offline case.

Nonconvex-strongly-concave minimax optimization has received increasing attentions in recent years [CHL$^+$23, NK17, ZYG$^+$21, LJJ20b, LJJ20a, ZXSL20, LYHZ20, LYC22, ZAG22, XWLP20]. In the scenario of single machine, [LJJ20b] showed the Stochastic Gradient Descent Ascent (`SGDA`) requires $\mathcal{O}(\kappa^3\epsilon^{-4})$ SFO complexity to find an ϵ-stationary point of $P(x)$, where the condition number is defined by $\kappa \triangleq L/\mu$. [LYHZ20] proposed the Stochastic Recursive gradiEnt Descent Ascent (`SREDA`), which uses the variance reduction technique of Stochastic Path Integrated Differential Estimator (`SPIDER`) [FLLZ18] to establish a SFO complexity of $\mathcal{O}(\min(\kappa^3\epsilon^{-3}, \sqrt{n}\kappa^2\epsilon^{-2}))$. It is worth noting that the $\mathcal{O}(\min(\epsilon^{-3}, \sqrt{n}\epsilon^{-2}))$ dependency on ϵ and n matches the lower bound of stochastic nonconvex optimization under the average-smooth assumption [ACD$^+$23, FLLZ18].

Distributed optimization is a popular setting for training large-scale machine learning models. It allows all agents on a given network to collaboratively optimize the global objective. In the decentralized scenario, each agent on the network only communicates with its neighbors. The decentralized training fashion avoids the communication traffic jam on the central node [LDS21]. There have been a lot of works focusing on the complexity of decentralized stochastic minimization problems [SLWY15, LCCC20, ULGN20, LLF22, YLY16, SLH20, XKK22, LLC22, CZS$^+$21, WZC$^+$21, KSR20, HBM21].

However, the understanding of the complexity of first-order methods decentralized nonconvex-strongly-concave minimax problems is still limited. For offline decentralized nonconvex-strongly-concave minimax problems, [THL20] proposed the Gradient-Tracking Descent-Ascent (`GT-DA`),

which combines multi-step gradient descent ascent gradient [NSH+19] with gradient tracking [NOS17, QL19]. GT-DA can provably find an ϵ-stationary point of $P(x)$ within $\widetilde{\mathcal{O}}(N\epsilon^{-2})$ SFO calls and $\widetilde{\mathcal{O}}(\epsilon^{-2})$ communication rounds. [ZLL+21] proposed the Gradient-Tracking Gradient Descent Ascent (GT-GDA) which updates both variable x and y simultaneously. The removal of the inner loop with respect to y also leads to the removal of the additional $\mathcal{O}(\log(1/\epsilon))$ factor in the complexity, and GT-DA can provably find an ϵ-stationary point of $P(x)$ within $\mathcal{O}(N\epsilon^{-2})$ SFO calls and $\mathcal{O}(\epsilon^{-2})$ communication rounds. However, both GT-DA and GT-GDA access the exact local gradients on each agent, which may be quite expensive when n is very large. To reduce the computation complexity, [ZLL+21] further proposed the Gradient Tracking-Stochastic Recursive Variance Reduction (GT-SRVR) by combining GT-GDA with SPIDER [FLLZ18]. GT-SRVR requires $\mathcal{O}(N + \sqrt{mN}\epsilon^{-2})$ SFO complexity to find an ϵ-stationary point of $P(x)$, outperforming GT-DA and GT-GDA when $n \gtrsim m$. However, for fixed N (total number of individual functions), the SFO upper bound of GT-SRVR will increase with the increase of m (number of agents). This trend seems somewhat unreasonable since involving more agents in the computation intuitively should not result in a higher overall computational cost.

For the online case, [XHZH21] introduced the variance reduction technique of STOchastic Recursive Momentum (STORM) [CO19] and proposed the Decentralized Minimax Hybrid Stochastic Gradient Descent (DM-HSGD) with an upper complexity bound of $\mathcal{O}(\kappa^3\epsilon^{-3})$ for both SFO calls and communication rounds. For this online case, The SFO complexity of DM-HSGD recovers the result of SREDA [LYHZ20] in the scenario of single-machine (when $m = 1$). Although the SFO complexity of DM-HSGD is better than those for GT-GDA and GT-SRVR when N has a higher order of magnitude compared to ϵ^{-1}, the communication complexity of $\mathcal{O}(\epsilon^{-3})$ in DM-HSGD is worse than the communication complexity of $\mathcal{O}(\epsilon^{-2})$ in GT-GDA and GT-SRVR. This implies DM-HSGD may has no advantage when the bottleneck is the cost of communication.

In many applications, the inner variable y in minimax problem (1) is often subject to some constraints, meaning that $\mathcal{Y}$ typically represents a given convex set endowed with a specific model. For instance, in adversarial training [GSS14], the variable y represents perturbations for the input, which typically lie within the box $\mathcal{Y} = \{y \in \mathbb{R}^{d_y} : \|y\|_\infty \leq c\}$ for some positive constant c. In distributionally robust optimization [YXL+19], the variable y represents the probability distribution in the simplex $\mathcal{Y} = \{y \in \mathbb{R}^{d_y} : \sum_k y_k = 1, y_k \geq 0\}$. Dealing with the constraint on variable y typically requires additional steps like projection, which lead to extra consensus error in the decentralized setting. However, existing variance-reduced methods for decentralized nonconvex-strongly-concave minimax problems including GT-SRVR and DM-HSGD only successfully deal with the unconstrained case.

In this paper, we propose a novel method called Decentralized Collaborative Recursive Optimization (DECOR) for solving decentralized nonconvex-strongly-concave minimax problems. We provide a unified convergence analysis for both the online and offline setups. Our analysis indicates that the proposed DECOR achieves the best-known complexity guarantee of both cases. We summarize the advantage of DECOR as follows.

- For the offline case, DECOR achieves the SFO complexity of $\mathcal{O}(N + \sqrt{N}\kappa^2\epsilon^{-2})$ and the communication complexity of $\widetilde{\mathcal{O}}(\kappa^2\epsilon^{-2})$. The SFO complexity of DECOR is strictly better than existing methods, and achieves a linear speed-up with respect to the number of agents m, which is better than GT-SRVR. The communication complexity of DECOR remains state-of-the-art, matching those of GT-DA/GT-GDA/GT-SRVR in the dependency of ϵ, up to logarithmic factors.

- For the online case, DECOR achieves the $\mathcal{O}(\kappa^3\epsilon^{-3})$ SFO complexity and the $\widetilde{\mathcal{O}}(\kappa^2\epsilon^{-2})$ communi-

cation complexity. The SFO complexity of DECOR is optimal in the dependency of ϵ [ACD+23]. And the communication complexity of DECOR strictly improves that of DM-HSGD in the dependency of both κ and ϵ.

- Moreover, DECOR is capable of working in both unconstrained and constrained scenarios, which gives it a wider range of applicability than previous variance-reduced methods GT-SRVR and DM-HSGD.

We compare our theoretical results with previous work in Table 1.

Notations. Throughout this paper, we denote $\|\cdot\|$ as the Frobenius norm of a matrix or the Euclidean norm of a vector. We use $I_m \in \mathbb{R}^{m\times m}$ to present a m by m identity matrix, $O_m \in \mathbb{R}^{m\times m}$ to present a m by m zero matrix, and let $\mathbf{1} = [1, \cdots, 1]^\top \in \mathbb{R}^m$. We define aggregated variables $\mathbf{x} \in \mathbb{R}^{m\times d_x}$, $\mathbf{y} \in \mathbb{R}^{m\times d_y}$ and $\mathbf{z} \in \mathbb{R}^{m\times(d_x+d_y)}$ for all agents as

$$\mathbf{x} = \begin{bmatrix} \mathbf{x}(1) \\ \vdots \\ \mathbf{x}(m) \end{bmatrix}, \quad \mathbf{y} = \begin{bmatrix} \mathbf{y}(1) \\ \vdots \\ \mathbf{y}(m) \end{bmatrix} \quad \text{and} \quad \mathbf{z} = \begin{bmatrix} \mathbf{z}(1) \\ \vdots \\ \mathbf{z}(m) \end{bmatrix}$$

where row vectors $\mathbf{x}(i) \in \mathbb{R}^{d_x}$ and $\mathbf{y}(i) \in \mathbb{R}^{d_y}$ are local variables on the i-th agent; and we also denote $\mathbf{z}(i) = [\mathbf{x}(i); \mathbf{y}(i)] \in \mathbb{R}^d$ with $d = d_x + d_y$. We use the lowercase with the bar to represent mean vector, e.g.,

$$\overline{x} = \frac{1}{m}\sum_{i=1}^m \mathbf{x}(i), \ \overline{y} = \frac{1}{m}\sum_{i=1}^m \mathbf{y}(i) \text{ and } \overline{z} = \frac{1}{m}\sum_{i=1}^m \mathbf{z}(i)$$

Similarly, we also introduce the aggregated gradient as

$$\nabla \mathbf{f}(\mathbf{z}) = \begin{bmatrix} \nabla f_1(\mathbf{x}(1), \mathbf{y}(1))^\top \\ \vdots \\ \nabla f_m(\mathbf{x}(m), \mathbf{y}(m))^\top \end{bmatrix} \in \mathbb{R}^{m\times d}$$

We use $\mathbb{I}[\,\cdot\,]$ to represent the indicator function of an event and define $n = +\infty$ for the online case.

2 Assumptions and Preliminaries

Throughout this paper, we suppose the stochastic NC-SC decentralized optimization problem (1) satisfies the following standard assumptions.

Assumption 2.1. *We suppose $P(x) \triangleq \max_{y\in\mathcal{Y}} f(x, y)$ is lower bounded. That is, we have*

$$P^* = \inf_{x\in\mathbb{R}^{d_x}} P(x) > -\infty$$

Assumption 2.2. *We suppose the stochastic component functions $F(x, y; \xi_i)$ on each agent is L-average smooth for some $L > 0$. That is, we have*

$$\begin{aligned} &\mathbb{E}\left\|\nabla F_i(x, y; \xi_i) - \nabla F_i(x', y'; \xi_i)\right\|^2 \\ &\le L^2\big(\left\|x - x'\right\|^2 + \left\|y - y'\right\|^2\big) \end{aligned}$$

for any $(x, y), (x', y') \in \mathbb{R}^{d_x\times d_y}$ and random index ξ_i.

Table 1. We compare the theoretical results of `DECOR` with previous methods for decentralized nonconvex-strongly-concave minimax optimization for both the offline and online settings. Notations κ^p and κ^q are used when the polynomial dependency on κ is not explicitly provided [ZLL+21, THL20]. The notation $\widetilde{\mathcal{O}}(\cdot)$ hides logarithmic factors in complexity. Note that `GT-GDA` and `GT-SRVR` only consider the unconstrained problem, which corresponds to the specific case in our setting where $\mathcal{Y} = \mathbb{R}^{d_y}$. The design of `DM-HSGD` includes the general constrained setting, but its convergence analysis for the constrained case looks problematic and we provide more detailed discussions in Section B.

Setup	Algorithm	#SFO	#Communication	Constraint
Offline	`GT-DA` [THL20]	$\widetilde{\mathcal{O}}\left(N\kappa^p\epsilon^{-2}\right)$	$\widetilde{\mathcal{O}}\left(\kappa^q\epsilon^{-2}\right)$	✓

  $\mathbf{a}^{(k+1)} = (1+\eta_a)W\mathbf{a}^{(k)} - \eta_a\mathbf{a}^{(k-1)}$
end for
Output: $\mathbf{a}^{(K)}$

Assumption 2.3. *We suppose each local function $f_i(x,y)$ is μ-strongly-concave in y. That is, there exists some constant $\mu > 0$ such that we have*

$$f_i(x,y) \le f_i(x,y') + \nabla_y f_i(x,y')^\top (y-y') - \frac{\mu}{2}\|y-y'\|^2$$

for any $x \in \mathbb{R}^{d_x}$ and $y, y' \in \mathbb{R}^{d_y}$.

Based on the smoothness and strong concavity assumptions, we can define the condition number of our optimization problem as follows.

Definition 2.1. *We define $\kappa \triangleq L/\mu$ as the condition number of problem (1), where L and μ are defined in Assumption 2.2 and 2.3 respectively.*

The differentiability of the primal function $P(x)$ can be proved by Danskin's theorem [LJJ20b, Lemma 4.3].

Proposition 2.1. *Under Assumptions 2.2 and 2.3, the function $P(x)$ is L_P-smooth with $L_P \triangleq (\kappa+1)L$ and its gradient can be written as $\nabla P(x) = \nabla_x f(x, y^*(x))$, where we define $y^*(x) \triangleq \arg\max_{y\in\mathcal{Y}} f(x,y)$.*

The differentiability of $P(x)$ allows us to define the ϵ-stationary point.

Definition 2.2. *We call $\widehat{x}$ an ϵ-stationary point if it holds that $\|\nabla P(\widehat{x})\| \le \epsilon$.*

The goal of algorithms is to find an ϵ stationary point of $P(x)$. In the setting of stochastic optimization, we suppose an algorithm can get access to the stochastic first-order oracle that satisfies the following assumptions. Note that the bounded variance assumption is only required for the online case.

Assumption 2.4. *We suppose each stochastic first-order oracle (SFO) $\nabla F_i(x,y;\xi_i)$ is unbiased and has bounded variance. That is, we have*

$$\mathbb{E}[\nabla F_i(x,y;\xi_i)] = \nabla f_i(x,y)$$

and

$$\mathbb{E}\,\|\nabla f_i(x,y) - \nabla F_i(x,y;\xi_i)\|^2 \le \sigma^2$$

with $\sigma^2 < +\infty$.

The mixing matrix tells us how the agents in the network communicate with their neighbors. We assume it satisfies the following assumption [SSPY23].

Assumption 2.5. *We suppose the matrix $W \in \mathbb{R}^{m\times m}$ have the following properties:*

a. *supported on the network: $W_{i,j} \ge 0$ if and only if i and j are connected in the network.*

b. *irreducible: W cannot be conjugated into block upper triangular form by a permutation matrix.*

c. *symmetric: $W = W^\top$.*

d. *doubly stochastic: $W\mathbf{1} = W^\top\mathbf{1} = \mathbf{1}$.*

e. *positive semidefinite: $W \succeq O_m$.*

Note that if a matrix W satisfies Assumption 2.5 a-d, we can let Assumption 2.5e be automatically satisfied by choosing $(W + I_m)/2$ to be the new mixing matrix.

By the Perron–Frobenius theorem, the eigenvalues of W can be sorted by

$$0 \le \lambda_m(W) \le \cdots \le \lambda_2(W) < \lambda_1(W) = 1$$

We then define the spectral gap of W as follows.

Definition 2.3. *For a matrix W that satisfies Assumption 2.5, we define the spectral gap as $\delta \triangleq 1 - \lambda_2(W)$.*

It is well known that the spectral gap of W is related to the mixing rate on the network.

Proposition 2.2 ([KSJ19, Lemma 16]). *Given a matrix W that satisfies Assumption 2.5, for any vector $\mathbf{a} \in \mathbb{R}^{m\times d}$, for the standard mixing iterate given by $\mathbf{a}^{(k+1)} = W\mathbf{a}^{(k)}$, we have*

$$\|W\mathbf{a} - \mathbf{1}\overline{\mathbf{a}}\| \leq (1-\delta)^K \|\mathbf{a} - \mathbf{1}\overline{\mathbf{a}}\|$$

where $\|\cdot\|$ is the Frobenius norm.

This simple mixing strategy is adopted by previous works including [THL20, XHZH21, ZLL+21], but it would lead to an unavoidable communication complexity dependency of at least $\mathcal{O}(1/\delta)$, which is suboptimal in the dependency of δ. To accelerate the mixing rate, we introduce the `FastMix` sub-procedure [LM11], which can lead to the optimal $\mathcal{O}(1/\sqrt{\delta}\,)$ dependency.

Proposition 2.3 ([YLZZ20, Proposition 1]). *Given a matrix W that satisfies Assumption 2.5, running Algorithm 1 ensures $\frac{1}{m}\mathbf{1}^\top \mathbf{a}^{(K)} = \overline{a}^{(0)}$ and*

$$\big\|\mathbf{a}^{(K)} - \mathbf{1}\overline{a}^{(0)}\big\| \leq c_1\big(1 - c_2\sqrt{\delta}\,\big)^K \big\|\mathbf{a}^{(0)} - \mathbf{1}\overline{a}^{(0)}\big\|$$

where $\overline{a}^{(0)} = \frac{1}{m}\mathbf{1}^\top\mathbf{a}^{(0)}$, $\|\cdot\|$ is the Frobenius norm, $c_1 = \sqrt{14}$ and $c_2 = 1 - 1/\sqrt{2}$.

To tackle the possible constraint in y, we define the projection and the constrained reduced gradient [Nes18].

Definition 2.4. *We define*

$$\Pi(y) \triangleq \arg\min_{y'\in\mathcal{Y}} \|y' - y\|^2 \text{ and } \mathbf{\Pi}(\mathbf{y}) \triangleq \arg\min_{\mathbf{y}'(i)\in\mathcal{Y}} \|\mathbf{y}' - \mathbf{y}\|^2$$

for $y \in \mathbb{R}^{d_y}$ and $\mathbf{y} \in \mathbb{R}^{m\times d_y}$ respectively.

Definition 2.5. *We also define the constrained reduced gradient of f at (x, y) with respect to y as*

$$G_\eta(x,y) = \frac{\Pi(y + \eta\nabla_y f(x,y)) - y}{\eta}$$

with some $0 < \eta \leq 1/L$.

3 The Proposed Algorithm

In this section, we propose a novel stochastic algorithm named Decentralized Collaborative Recursive Optimization (`DECOR`) for decentralized nonconvex-strongly-concave minimax problems. We provide a unified framework for analyzing our `DECOR` for both online and offline cases. It shows the algorithm can find an ϵ-stationary point of $P(x)$ within at most $\mathcal{O}(\kappa^3\epsilon^{-3})$ and $\mathcal{O}(N + \sqrt{N}\kappa^2\epsilon^{-2})$ SFO calls for the online and offline setting respectively; and both of two settings require at most $\mathcal{O}(\kappa^2\epsilon^{-2}\log m/\sqrt{\delta})$ communication rounds.

Algorithm 2 Decentralized Collaborative Recursive Optimization (DECOR)

1: **Notations:** Let $\mathbf{z}_t = [\mathbf{x}_t, \mathbf{y}_t] \in \mathbb{R}^{m\times d}$ and $\mathbf{s}_t = [\mathbf{u}_t, \mathbf{v}_t] \in \mathbb{R}^{m\times d}$
2: **Input:** initial parameter $\overline{z}_0 \in \mathbb{R}^d$, stepsize $\eta > 0$, stepsize ratio $\gamma \in (0, 1]$, probability $p \in (0, 1]$, small mini-batch size b, large mini-batch size b' (we set $b' = n$ for the offline case), initial communication rounds K_0, small communication rounds K, large communication rounds K'.
3: $\mathbf{z}_0 = \mathbf{1}\overline{z}_0$
4: **parallel for** $i = 1, \ldots, m$ **do**
5: Sample $\mathcal{S}_0(i) = \begin{cases} \{\xi_{i,1}, \ldots, \xi_{i,b'}\} \text{ i.i.d.} & \text{online case} \\ \{\xi_{i,1}, \ldots, \xi_{i,n}\} & \text{offline case} \end{cases}$
6: $\mathbf{g}_0(i) = \dfrac{1}{b'} \displaystyle\sum_{\xi_{i,j}\in\mathcal{S}_0(i)} \nabla F_i(\mathbf{z}_0(i); \xi_{i,j})$
7: **end parallel for**
8: $\mathbf{s}_0 = \texttt{FastMix}(\mathbf{g}_0, K_0)$
9: **for** $t = 0, \ldots, T-1$ **do**
10: Sample $\zeta_t \sim$ Bernoulli(p)
11: $\mathbf{x}_{t+1} = \texttt{FastMix}\big(\mathbf{x}_t - \gamma\eta\mathbf{u}_t, K\big)$
12: $\mathbf{y}_{t+1} = \texttt{FastMix}\big(\mathbf{\Pi}(\mathbf{y}_t + \eta\mathbf{v}_t), K\big)$
13: **parallel for** $i = 1, \ldots, m$ **do**
14: **if** $\zeta_t = 1$ **do**
15: Sample $\mathcal{S}'_t(i) = \begin{cases} \{\xi_{i,1}, \ldots, \xi_{i,b'}\} \text{ i.i.d.} & \text{online case} \\ \{\xi_{i,1}, \ldots, \xi_{i,n}\} & \text{offline case} \end{cases}$
16: $\mathbf{g}_{t+1}(i) = \dfrac{1}{b'} \displaystyle\sum_{\xi_{i,j}\in\mathcal{S}'_t(i)} \nabla F_i(\mathbf{z}_{t+1}(i); \xi_{i,j})$
17: **else**
18: Sample $\omega_t(i) \sim$ Bernoulli(q)
19: Sample $\mathcal{S}_t(i) = \{\xi_{i,1}, \ldots, \xi_{i,b}\}$ i.i.d.
20: $\mathbf{g}_{t+1}(i) = \mathbf{g}_t(i) + \dfrac{\omega_t(i)}{bq} \displaystyle\sum_{\xi_{i,j}\in\mathcal{S}_t(i)} \big(\nabla F_i(\mathbf{z}_{t+1}(i); \xi_{i,j}) - \nabla F_i(\mathbf{z}_t(i); \xi_{i,j})\big)$
21: **end if**
22: **end parallel for**
23: $\mathbf{s}_{t+1} = \begin{cases} \texttt{FastMix}\big(\mathbf{s}_t + \mathbf{g}_{t+1} - \mathbf{g}_t, K'\big), & \text{if } \zeta_t = 1 \\ \texttt{FastMix}\big(\mathbf{s}_t + \mathbf{g}_{t+1} - \mathbf{g}_t, K\big), & \text{if } \zeta_t = 0 \end{cases}$
24: **end for**
25: **Output:** x_{out} by uniformly sampling from $\{\mathbf{x}_0(1), \mathbf{x}_0(2), \cdots, \mathbf{x}_{T-1}(m)\}$

3.1 Method Overview

DECOR constructs stochastic recursive gradients $\mathbf{g}_t(i)$ [FLLZ18, NLST17, LBZR21, LYHZ20] to estimate the local gradients, *i.e.* $\mathbf{g}_t(i) \approx \nabla f_i(\mathbf{z}_t(i))$. This step (Line 22 in Algorithm 2) reduces the variance of stochastic gradient estimators on each agent, leading to the optimal $\mathcal{O}(\epsilon^{-3})$ dependency in the SFO upper complexity bound. DECOR then applies the gradient tracking technique [QL19, DLS16] to track the average gradient over the network via the gradient tracker $\mathbf{s}_t(i)$, *i.e.* $\mathbf{s}_t(i) \approx \nabla f(\mathbf{z}_t(i))$. The gradient tracker $\mathbf{s}_t(i)$ is also updated in a recursive way (Line 24 in Algorithm 2). This step is commonly used to achieve convergence when the data distribution on each agent

does not satisfy the i.i.d assumption in decentralized optimization [NOS17, SSPY23]. With the gradient tracker, DECOR applies the two-timescale gradient descent ascent [LJJ20b] to solve the maximization of y and minimization of x simultaneously (Line 13-14 in Algorithm 2). The random variable $\zeta_t \sim \text{Bernoulli}(p)$ (Line 12 in Algorithm 2) decides the batch size and the number of consensus steps in the iteration. By appropriately choosing the probability p, batch sizes b, b', and consensus steps K, K', DECOR achieves the best-known computation complexity and communication complexity trade-off in decentralized nonconvex-strongly-concave minimax optimization.

3.2 A Novel Lyapunov Function

Different from previous works [ZLL$^+$21, XHZH21, LYHZ20], we propose a novel Lyapunov function as follows:

$$\Phi_t \triangleq \Psi_t + \frac{1}{m\eta} C_t + \frac{\eta}{mp} V_t + \frac{\eta}{p} U_t, \quad \text{where} \tag{4}$$

$$\Psi_t = P(\overline{x}_t) - P^* + \alpha(P(\overline{x}_t) - f(\overline{x}_t, \overline{y}_t)) \tag{5}$$

$$C_t = \|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2 + \eta^2 \|\mathbf{s}_t - \mathbf{1}\overline{s}_t\|^2 \tag{6}$$

$$V_t = \frac{1}{m}\|\mathbf{g}_t - \nabla \mathbf{f}(\mathbf{z}_t)\|^2 \quad \text{and} \tag{7}$$

$$U_t = \left\| \frac{1}{m} \sum_{i=1}^{m} (\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i))) \right\|^2 \tag{8}$$

We set $\alpha \in (0, 1]$ in later analysis. Below, we illustrate the meaning of each quantity in the Lyapunov function.

- Ψ_t measures the optimization error. The gradient descent ascent step ensures that Ψ_t can decrease monotonically at each iteration [YKH20, CYL22].
- C_t measures the consensus error, which can be bounded by the properties of gradient tracking and consensus steps [SSPY23].
- V_t and U_t measure the variance of $\mathbf{g}_t$, which can be bounded by the property of martingale [FLLZ18, LYHZ20]. We provide a detailed discussion for the roles of V_t and U_t after Lemma 3.3 and 3.4.

We can show that C_t, V_t, and U_t are sufficiently small during the iterations, which allows us to analyze DECOR by analogizing gradient descent ascent on the mean variables $\overline{x}_t$ and $\overline{y}_t$ with some small noise.

Remark 3.1. *Our Lyapunov function Φ_t characterizes the sub-optimality of the maximization problem $\max_{y\in\mathcal{Y}} f(\overline{x}_t, y)$ by $P(\overline{x}_t) - f(\overline{x}_t, \overline{y}_t)$, which is easy to be analyzed for stochastic variance reduced algorithm in the decentralized setting. In contrast, [XHZH21] and [ZLL$^+$21] measure the sub-optimality by $\|\overline{y}_t - y^*(\overline{x}_t)\|^2$, which leads to their analysis be more complicated than ours.*

3.3 Convergence Analysis

Our analysis starts from the following descent lemma.

Lemma 3.1. *For Algorithm 2, we set the parameters by $\eta \leq 1/(4L)$ and*

$$\gamma = \frac{\alpha}{(1+\alpha)128\kappa^2} \tag{9}$$

Then for any $\alpha > 0$ it holds that

$$\begin{aligned}\mathbb{E}[\Psi_{t+1}] \leq \Psi_t - \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \frac{1}{8\gamma\eta}\mathbb{E}\|\overline{x}_{t+1} - \overline{x}_t\|^2 \\ - \frac{\alpha}{16\eta}\mathbb{E}\|\overline{z}_{t+1} - \overline{z}_t\|^2 + 6\alpha\eta U_t + \frac{3\alpha}{m\eta}C_t\end{aligned}$$

If both C_t and U_t are sufficiently small, the above lemma indicates that the optimization error decreases by roughly $(\gamma\eta/2)\|\nabla P(\overline{x}_t)\|^2$ at each step in expectation and the remaining proof can follow the gradient descent [Nes18, Bub15] on the primal function $P(x)$.

Recall Proposition 2.3. We further define the discount factors of consensus error that arises from mixing steps (Line 10, 13, 14 and 24 in Algorithm 2) as:

$$\rho_0 = c_1\big(1 - c_2\sqrt{\delta}\big)^{K_0} \tag{10}$$

$$\rho' = c_1\big(1 - c_2\sqrt{\delta}\big)^{K'} \tag{11}$$

$$\rho = c_1\big(1 - c_2\sqrt{\delta}\big)^{K} \tag{12}$$

Then we can bound the consensus error as follows.

Lemma 3.2. *For Algorithm 2, let $\rho^2 \leq 1/24$. Then*

$$\begin{aligned}\mathbb{E}[C_{t+1}] \leq & 12c\rho^2 C_t + 6\rho'^2\eta^2 m V_t + 2c\rho^2 m\mathbb{E}\|\overline{z}_{t+1} - \overline{z}_t\|^2 \\ & + \frac{6\rho'^2 m\eta^2\sigma^2}{b'}\mathbb{I}[b' < n]\end{aligned}$$

where we define $c = \max\{1/(bq), 1\}$.

Remark 3.2. *For convenience, we define $n = +\infty$ for the online case and $b' = n$ for the offline case. Then*

$$\mathbb{I}[b' < n] = \begin{cases} 1, & \textit{for online case} \\ 0, & \textit{for offline case} \end{cases}$$

This notation allows us to present the analysis for both cases in one unified framework.

Lemma 3.1 and 3.2 mean the decrease of the optimization error Ψ_t and consensus error C_t requires the reasonable upper bounds of V_t and U_t, which can be characterized by the following recursions.

Lemma 3.3. *For Algorithm 2, we have*

$$\begin{aligned}\mathbb{E}[V_{t+1}] \leq (1-p)V_t + \frac{4(1-p)L^2}{mbq}C_t \\ + \frac{p\sigma^2}{b'}\mathbb{I}[b' < n] + \frac{3(1-p)L^2}{bq}\mathbb{E}\|\overline{z}_{t+1} - \overline{z}_t\|^2\end{aligned}$$

Lemma 3.4. *For Algorithm 2, we have*

$$\mathbb{E}[U_{t+1}] \le (1-p)U_t + \frac{4(1-p)L^2}{m^2bq}C_t + \frac{p\sigma^2}{mb'}\mathbb{I}[b' < n] + \frac{3(1-p)L^2}{mbq}\mathbb{E}\|\overline{z}_{t+1} - \overline{z}_t\|^2$$

Note that for any vector sequence $a_1, \cdots, a_m$ we always have $\|\sum_{i=1}^m a_i\|^2 \le m\sum_{i=1}^m \|a_i\|^2$, which directly implies $U_t \le V_t$. Therefore one can use the quantity V_t only in the analysis as [ZLL+21], but the separation of U_t and V_t makes our bound tighter. As a consequence, we show a linear speed-up in the SFO complexity with respect to the number of agents m which was not shown by [ZLL+21].

Putting Lemma 3.1, 3.2 and 3.3 together, we can prove the main result for `DECOR` as follows.

Theorem 3.1. *For Algorithm 2 , we set parameters*

$$\eta = \frac{1}{48L}, \quad b = \left\lceil \sqrt{\frac{b'}{m}} \right\rceil, \quad q = \frac{1}{b}\sqrt{\frac{b'}{m}}, \quad p = \frac{bq}{bq+b'} \tag{13}$$

$$T = \left\lceil \frac{16\Psi_0}{\gamma\eta\epsilon^2} + \frac{2}{p} \right\rceil, \quad K_0 = \left\lceil \frac{\log\left(16c_1/(\gamma m\epsilon^2)\right)}{c_2\sqrt{\delta}} \right\rceil \tag{14}$$

$$K = \left\lceil \frac{5\log(c_1(m/b'+1))}{c_2\sqrt{\delta}} \right\rceil, \quad K' = \left\lceil \frac{5\log(c_1 m)}{c_2\sqrt{\delta}} \right\rceil \tag{15}$$

where c_1, c_2 are defined in Proposition 2.3, $\gamma = \Theta(\kappa^{-2})$ follows (9), $\alpha = 1/8$ and

$$b' = \begin{cases} \lceil 32\sigma^2/(\gamma m\epsilon^2) \rceil, & \text{for online case} \\ n, & \text{for offline case} \end{cases} \tag{16}$$

Then the output satisfies $\mathbb{E}\|\nabla P(x_{\text{out}})\| \le \epsilon$ within the overall SFO complexity

$$\begin{cases} \mathcal{O}\big(\kappa^2\sigma^2\epsilon^{-2} + \kappa^3 L\sigma\epsilon^{-3}\big), & \text{for online case} \\ \mathcal{O}\big(mn + \sqrt{mn}\kappa^2 L\epsilon^{-2}\big), & \text{for offline case;} \end{cases}$$

and communication complexity $\mathcal{O}((\kappa^2 L\epsilon^{-2}\log m)/\sqrt{\delta}\,)$.

This theorem shows that `DECOR` achieves the best-known complexity guarantee both in computation and communication, either for online or offline cases.

4 Conclusion, Discussions and Future Work

In this paper, we introduced `DECOR` (Decentralized Collaborative Recursive Optimization), an efficient stochastic algorithm for decentralized nonconvex-strongly-concave minimax optimization. Leveraging gradient tracking and variance reduction techniques, `DECOR` achieves optimal complexity in both online and offline settings, efficiently addressing constrained and unconstrained minimax problems. Our theoretical analysis demonstrated that `DECOR` attains the best-known SFO complexity of $\mathcal{O}(\min(\kappa^3\epsilon^{-3}, \kappa^2\sqrt{N}\epsilon^{-2}))$ and communication complexity of $\widetilde{\mathcal{O}}(\kappa^2\epsilon^{-2})$.

A future direction is to improve decentralized stochastic algorithms by reducing the condition number κ dependency through multiple-looped techniques, similar to approaches in single-machine settings. Additionally, it would be valuable to explore decentralized minimax optimization for nonconvex-non-strongly-concave objectives or more general nonconvex-nonconcave problems. Recent studies have extended these problem setups, although none surpass the convergence rates established in this paper. For example, [Xu23] examines more general regularizers but only in the offline setting, resulting in worse complexity. Likewise, [MBX23] considers stochastic optimization but remains limited to the offline case, with higher computational complexity. Meanwhile, [HC23] extends the analysis to online cases under the Polyak–Łojasiewicz (PL) condition, but with inferior communication complexity compared to our results.

A Some Useful Lemmas

We first provide some useful lemmas.

Lemma A.1. *For any $a_1, \ldots, a_m \in \mathbb{R}^d$, we have*

$$\left\| \frac{1}{m} \sum_{i=1}^{m} a_i \right\|^2 \leq \frac{1}{m} \sum_{i=1}^{m} \|a_i\|^2$$

Lemma A.2. *For any matrix $\mathbf{z} \in \mathbb{R}^{m \times d}$ and $\overline{z} = \frac{1}{m}\mathbf{1}^\top \mathbf{z}$, we have*

$$\|\mathbf{z} - \mathbf{1}\overline{z}\| \leq \|\mathbf{z}\|$$

Lemma A.3. *Under Assumption 2.2, we have*

$$\left\|\nabla \mathbf{f}(\mathbf{z}) - \nabla \mathbf{f}(\mathbf{z}')\right\| \leq L \left\|\mathbf{z} - \mathbf{z}'\right\|$$

for any $\mathbf{z}, \mathbf{z}' \in \mathbb{R}^{m \times d}$.

Lemma A.4. *For Algorithm 2, we have $\overline{s}_t = \frac{1}{m}\mathbf{1}^\top \mathbf{g}_t = \overline{g}_t$.*

Proof. We prove this lemma by induction. For $t = 0$, we have

$$\overline{s}_0 = \frac{1}{m}\mathbf{1}^\top \mathbf{s}_0 = \frac{1}{m}\mathbf{1}^\top \mathbf{g}_0$$

Suppose the statement holds for $t \leq k$. Then for $t = k+1$, the induction base means that

$$\begin{aligned}
&\overline{s}_{k+1} \\
=&\overline{s}_k + \overline{g}_{k+1} - \overline{g}_k \\
=&\frac{1}{m}\mathbf{1}^\top \mathbf{g}(\mathbf{z}_k) + \overline{g}_{k+1} - \frac{1}{m}\mathbf{1}^\top \mathbf{g}(\mathbf{z}_k) \\
=&\overline{g}_{k+1} \\
=&\frac{1}{m}\mathbf{1}^\top \mathbf{g}_{k+1}
\end{aligned}$$

which finished the proof. □

Lemma A.5. *Under Assumption 2.2, for Algorithm 2, it holds that*

$$\|\overline{s}_t - \nabla f(\overline{z}_t)\|^2 \leq 2\left\|\frac{1}{m}\sum_{i=1}^m (\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i)))\right\|^2 + \frac{2L^2}{m}\|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2$$

Proof. Using Young's inequality and Assumption 2.2, we have

$$\begin{aligned}
&\|\overline{s}_t - \nabla f(\overline{z}_t)\|^2 \\
=&\left\|\frac{1}{m}\sum_{i=1}^m \left(\mathbf{g}_t(i) - \nabla f_i(\overline{z}_t)\right)\right\|^2 \\
\leq&2\left\|\frac{1}{m}\sum_{i=1}^m (\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i)))\right\|^2 + 2\left\|\frac{1}{m}\sum_{i=1}^m (\nabla f_i(\mathbf{z}_t(i)) - \nabla f_i(\overline{z}_t))\right\|^2 \\
\leq&2\left\|\frac{1}{m}\sum_{i=1}^m (\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i)))\right\|^2 + \frac{2}{m}\sum_{i=1}^m \|\nabla f_i(\mathbf{z}_t(i)) - \nabla f_i(\overline{z}_t)\|^2 \\
\leq&2\left\|\frac{1}{m}\sum_{i=1}^m (\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i)))\right\|^2 + \frac{2L^2}{m}\|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2
\end{aligned}$$

□

Lemma A.6. *When $f(x, y)$ is L-smooth and μ-strongly-concave in y, it holds that*

$$\|\nabla P(x) - \nabla_x f(x, y)\| \leq 2\kappa\|G_\eta(x, y)\|$$

where $G_\eta(x, y)$ denotes the constrained reduced gradient

$$G_\eta(x, y) = \frac{\Pi(y + \eta\nabla_y f(x, y)) - y}{\eta}$$

with any $\eta \leq 1/L$.

Proof. Using the Danskin's theorem, i.e. $\nabla P(x) = \nabla_x f(x, y^*(x))$ as well as the L-smoothness, we have

$$\|\nabla P(x) - \nabla_x f(x, y)\| \leq L\|y^*(x) - y\| \tag{17}$$

The Corollary 1 of [LYHZ20, Appendix A] tells us

$$\mu\|y - y^*(x)\| \leq 2\|G_\eta(x, y)\| \tag{18}$$

We prove this lemma by combing inequalities (17) and (18). □

B Discussions on DM-HSGD

Decentralized Minimax Hybrid Stochastic Gradient Descent (DM-HSGD) considers the minimax problem (1) in both unconstrained and constrained cases [XHZH21]. However, the theoretical analysis of this method only works for unconstrained case, and it is problematic for the general constrained case.[1]

The analysis of DM-HSGD heavily relies on its Lemma 5 [XHZH21, Appendix A.2]. However, the proof of this result is based on the following equation [XHZH21, Equation (29)][2]

$$2\eta_y\langle \overline{u}_t, \widehat{y}_t - \overline{y}_t\rangle = \|\overline{y}_t - \widehat{y}_t\|^2 + \|\overline{y}_{t+1} - \overline{y}_t\|^2 - \|\overline{y}_{t+1} - \widehat{y}_t\|^2 \tag{19}$$

where $\widehat{y}_t = \arg\max_{y\in\mathcal{Y}} f(\overline{x}_t, y)$ corresponds to $y^*(\overline{x}_t)$ in our notations. Note that Equation (19) does not hold for general convex and compact set $\mathcal{Y}$. We further illustrate this below.

We denote $\mathbf{y}_{t+1/2} = \mathbf{y}_t + \eta_y \mathbf{u}_t$ by following [XHZH21]'s notation. The procedure of DM-HSGD guarantees that $\overline{y}_{t+1} = \overline{\Pi}(\mathbf{y}_{t+1/2})$, then we have

$$2\eta_y\langle \overline{u}_t, \widehat{y}_t - \overline{y}_t\rangle = 2\langle \overline{y}_{t+1/2} - \overline{y}_t, \widehat{y}_t - \overline{y}_t\rangle = \|\overline{y}_t - \widehat{y}_t\|^2 + \|\overline{y}_{t+1/2} - \overline{y}_t\|^2 - \|\overline{y}_{t+1/2} - \widehat{y}_t\|^2 \tag{20}$$

The only difference between equations (19) and (20) is their last terms. In the unconstrained case that $\mathcal{Y} = \mathbb{R}^{d_y}$, it holds that

$$\overline{y}_{t+1} = \overline{\Pi}(\mathbf{y}_{t+1/2}) = \overline{y}_{t+1/2} \tag{21}$$

which leads to

$$\|\overline{y}_{t+1} - \widehat{y}_t\|^2 = \|\overline{y}_{t+1/2} - \widehat{y}_t\|^2$$

However, the equation (21) may not hold in the constrained case, since we can not guarantee $\overline{\Pi}(\mathbf{y}) = \overline{y}$ in general. For example, consider that

$$\mathcal{Y} = \{y \in \mathbb{R}^2 : \|y\|^2 = 2\}, \qquad \mathbf{y}(1) = (2, 2) \qquad \text{and} \qquad \mathbf{y}(2) = (2, -2)$$

then we can have $\overline{y} = (2, 0)$ while $\overline{\Pi}(\mathbf{y}) = \big(\sqrt{2}, 0\big)$.

For the analysis of projected first-order methods for constrained problems (even for minimization problems), we typically introduce the constrained reduced gradient [Nes18, Definition 2.2.3] and

[1] The theoretical issue of DM-HSGD has also been mentioned by [ZMBAX23].

[2] The analysis of DM-HSGD uses η_y and $\overline{u}_t$ to present the stepsize and gradient estimator with respect to y, which play the similar roles of η and $\overline{v}_t$ in our notations.

apply the first-order optimality condition (such as Equation (33) in Section C) to establish the convergence results. However, such popular techniques are not included in the analysis of DM-HSGD.

In decentralized setting, the extension from unconstrained case to constrained case is non-trivial, since the projection step introduces additional consensus error. As a consequence, our analysis is essentially different from the [XHZH21]. We design a novel Lyapunov function and present the details in Lemma 3.1 to address this issue.

C The Proof of Lemma 3.1

Proof. Denote $\mathbf{y}'_{t+1} = \mathbf{\Pi}(\mathbf{y}_t + \eta \mathbf{v}_t)$. By Proposition 2.3, the update rules of $\mathbf{x}_t, \mathbf{y}_t$ means

$$\overline{x}_{t+1} = \overline{x}_t - \gamma\eta\overline{u}_t \qquad \text{and} \qquad \overline{y}_{t+1} = \overline{y}'_{t+1} = \overline{\Pi}(\mathbf{y}_t + \eta\mathbf{v}_t) \tag{22}$$

In the view of inexact gradient descent on $P(x)$, it yields

$$\mathbb{E}[P(\overline{x}_{t+1})] \tag{23}$$
$$\leq \mathbb{E}\left[P(\overline{x}_t) + \nabla P(\overline{x}_t)^\top(\overline{x}_{t+1} - \overline{x}_t) + \frac{L_P}{2}\|\overline{x}_{t+1} - \overline{x}_t\|^2\right] \tag{24}$$
$$= \mathbb{E}\left[P(\overline{x}_t) - \gamma\eta\nabla P(\overline{x}_t)^\top\overline{u}_t + \frac{L_P\gamma^2\eta^2}{2}\|\overline{u}_t\|^2\right] \tag{25}$$
$$= \mathbb{E}\left[P(\overline{x}_t) - \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \left(\frac{\gamma\eta}{2} - \frac{L_P\gamma^2\eta^2}{2}\right)\|\overline{u}_t\|^2 + \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t) - \overline{u}_t\|^2\right] \tag{26}$$
$$\leq \mathbb{E}\left[P(\overline{x}_t) - \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \left(\frac{\gamma\eta}{2} - \frac{L_P\gamma^2\eta^2}{2}\right)\|\overline{u}_t\|^2\right] \tag{27}$$
$$+ \mathbb{E}\left[\frac{\gamma\eta}{m}\sum_{i=1}^m\|\nabla P(\overline{x}_t) - \nabla_x f(\overline{x}_t, \mathbf{y}_t(i))\|^2 + \frac{\gamma\eta}{m}\sum_{i=1}^m\|\overline{u}_t - \nabla_x f(\overline{x}_t, \mathbf{y}_t(i))\|^2\right] \tag{28}$$
$$\leq \mathbb{E}\left[P(\overline{x}_t) - \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \left(\frac{\gamma\eta}{2} - \frac{L_P\gamma^2\eta^2}{2}\right)\|\overline{u}_t\|^2\right] \tag{29}$$
$$+ \mathbb{E}\left[\frac{4\kappa^2\gamma\eta}{m}\sum_{i=1}^m\|G_\eta(\overline{x}_t, \mathbf{y}_t(i))\|^2 + \frac{\gamma\eta}{m}\sum_{i=1}^m\|\overline{u}_t - \nabla_x f(\overline{x}_t, \mathbf{y}_t(i))\|^2\right] \tag{30}$$
$$\leq \mathbb{E}\left[P(\overline{x}_t) - \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \left(\frac{\gamma\eta}{2} - \frac{L_P\gamma^2\eta^2}{2}\right)\|\overline{u}_t\|^2\right] \tag{31}$$
$$+ \mathbb{E}\left[\frac{8\kappa^2\gamma\eta}{m}\sum_{i=1}^m\|\mathbf{v}'_t(i)\|^2 + \frac{8\kappa^2\gamma\eta}{m}\sum_{i=1}^m\|\mathbf{v}_t(i) - \nabla_y f(\overline{x}_t, \mathbf{y}_t(i))\|^2 + \frac{\gamma\eta}{m}\sum_{i=1}^m\|\overline{u}_t - \nabla_x f(\overline{x}_t, \mathbf{y}_t(i))\|^2\right] \tag{32}$$

where $\mathbf{v}'_t(i) = (\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i))/\eta$. Above, the first inequality follows from the smoothness of $P(x)$ by Proposition 2.1; the second one is due to the Young's inequality; the third inequality holds according to Lemma A.6; in the last one we use the Young's inequality along with

$$\begin{aligned}&\|\mathbf{v}'_t(i) - G_\eta(\overline{x}_t, \mathbf{y}_t(i))\| \\ =& \frac{1}{\eta}\|\Pi(\mathbf{y}_t + \eta\mathbf{v}_t(i)) - \Pi(\mathbf{y}_t + \eta\nabla_y f(\overline{x}_t, \mathbf{y}_t(i)))\|\end{aligned}$$

$$\leq \|\mathbf{v}_t(i) - \nabla_y f(\overline{x}_t, \mathbf{y}_t(i))\|$$

Recall that $\mathbf{y}'_{t+1} = \mathbf{\Pi}(\mathbf{y}_t + \eta \mathbf{v}_t)$ and the first-order optimality of the projection, we have

$$(\mathbf{y}_t(i) + \eta \mathbf{v}_t(i) - \mathbf{y}'_{t+1}(i))^\top (y - \mathbf{y}'_{t+1}(i)) \leq 0 \tag{33}$$

for any $y \in \mathcal{Y}$. Taking $y = \overline{y}_t$ in above inequality, we get

$$\begin{aligned}
&\mathbf{v}_t(i)^\top (\overline{y}_t - \mathbf{y}'_{t+1}(i)) && (34)\\
&\leq \frac{1}{\eta} (\overline{y}_t - \mathbf{y}'_{t+1}(i))^\top (\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)) && (35)\\
&= \frac{1}{2\eta} \|\overline{y}_t - \mathbf{y}_t(i)\|^2 - \frac{1}{2\eta} \|\overline{y}_t - \mathbf{y}'_{t+1}(i)\|^2 - \frac{1}{2\eta} \|\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)\|^2 && (36)
\end{aligned}$$

In the view of inexact gradient descent ascent on $f(x, y)$, it yields

$$\begin{aligned}
&\mathbb{E}[-f(\overline{x}_{t+1}, \mathbf{y}'_{t+1}(i))]\\
&\leq \mathbb{E}\left[-f(\overline{x}_{t+1}, \mathbf{y}_t(i)) - \nabla_y f(\overline{x}_{t+1}, \mathbf{y}_t(i))^\top (\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)) + \frac{L}{2} \|\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)\|^2\right]\\
&\leq \mathbb{E}\left[-f(\overline{x}_t, \mathbf{y}_t(i)) - \nabla_x f(\overline{x}_t, \mathbf{y}_t(i))^\top (\overline{x}_{t+1} - \overline{x}_t) + \frac{L}{2} \|\overline{x}_{t+1} - \overline{x}_t\|^2\right]\\
&\quad + \mathbb{E}\left[-\nabla_y f(\overline{x}_{t+1}, \mathbf{y}_t(i))^\top (\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)) + \frac{L}{2} \|\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)\|^2\right]\\
&\leq \mathbb{E}\left[-f(\overline{x}_t, \overline{y}_t) + \nabla_y f(\overline{x}_t, \mathbf{y}_t(i))^\top (\overline{y}_t - \mathbf{y}_t(i)) - \nabla_x f(\overline{x}_t, \mathbf{y}_t(i))^\top (\overline{x}_{t+1} - \overline{x}_t) + \frac{L}{2} \|\overline{x}_{t+1} - \overline{x}_t\|^2\right]\\
&\quad + \mathbb{E}\left[-\nabla_y f(\overline{x}_{t+1}, \mathbf{y}_t(i))^\top (\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)) + \frac{L}{2} \|\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)\|^2\right]\\
&= \mathbb{E}\left[-f(\overline{x}_t, \overline{y}_t) + \nabla_y f(\overline{x}_t, \mathbf{y}_t(i))^\top (\overline{y}_t - \mathbf{y}'_{t+1}(i)) - \nabla_x f(\overline{x}_t, \mathbf{y}_t(i))^\top (\overline{x}_{t+1} - \overline{x}_t) + \frac{L}{2} \|\overline{x}_{t+1} - \overline{x}_t\|^2\right]\\
&\quad + \mathbb{E}\left[(\nabla_y f(\overline{x}_t, \mathbf{y}_t(i)) - \nabla_y f(\overline{x}_{t+1}, \mathbf{y}_t(i)))^\top (\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)) + \frac{L}{2} \|\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)\|^2\right]\\
&= \mathbb{E}\left[-f(\overline{x}_t, \overline{y}_t) + \mathbf{v}_t(i)^\top (\overline{y}_t - \mathbf{y}'_{t+1}(i)) - \nabla_x f(\overline{x}_t, \mathbf{y}_t(i))^\top (\overline{x}_{t+1} - \overline{x}_t) + \frac{L}{2} \|\overline{x}_{t+1} - \overline{x}_t\|^2\right]\\
&\quad + \mathbb{E}\left[(\nabla_y f(\overline{x}_t, \mathbf{y}_t(i)) - \nabla_y f(\overline{x}_{t+1}, \mathbf{y}_t(i)))^\top (\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)) + \frac{L}{2} \|\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)\|^2\right]\\
&\quad + \mathbb{E}\left[(\nabla_y f(\overline{x}_t, \mathbf{y}_t(i)) - \mathbf{v}_t(i))^\top (\overline{y}_t - \mathbf{y}'_{t+1}(i))\right]\\
&\leq \mathbb{E}\left[-f(\overline{x}_t, \overline{y}_t) - \frac{1}{2\eta} \|\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)\|^2 - \nabla_x f(\overline{x}_t, \mathbf{y}_t(i))^\top (\overline{x}_{t+1} - \overline{x}_t) + \frac{L}{2} \|\overline{x}_{t+1} - \overline{x}_t\|^2\right]\\
&\quad + \mathbb{E}\left[(\nabla_y f(\overline{x}_t, \mathbf{y}_t(i)) - \nabla_y f(\overline{x}_{t+1}, \mathbf{y}_t(i)))^\top (\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)) + \frac{L}{2} \|\mathbf{y}'_{t+1}(i) - \mathbf{y}_t(i)\|^2\right]\\
&\quad + \mathbb{E}\left[\frac{\eta}{2} \|\nabla_y f(\overline{x}_t, \mathbf{y}_t(i)) - \mathbf{v}_t(i))\|^2 + \frac{1}{2\eta} \|\overline{y}_t - \mathbf{y}_t(i)\|^2\right]\\
&\leq \mathbb{E}\left[-f(\overline{x}_t, \overline{y}_t) - \left(\frac{\eta}{4} - \frac{\eta^2 L}{2}\right) \|\mathbf{v}'_t(i)\|^2 + \left(\frac{\gamma^2 \eta^2 L}{2} + \gamma^2 \eta^3 L^2 + \frac{3\gamma^2 \eta}{2}\right) \|\overline{u}_t\|^2\right]
\end{aligned}$$

$$+\mathbb{E}\left[\frac{\eta}{2}\|\nabla_x f(\overline{x}_t,\mathbf{y}_t(i))-\overline{u}_t\|^2+\frac{\eta}{2}\|\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))-\mathbf{v}_t(i))\|^2+\frac{1}{2\eta}\|\overline{y}_t-\mathbf{y}_t(i)\|^2\right],$$

where $\mathbf{v}'_t(i)=(\mathbf{y}'_{t+1}(i)-\mathbf{y}_t(i))/\eta$. Above, the equations rely on rearranging the terms; the first two inequalities are based on the L-smoothness of the objective $f(x,y)$. The third one follows from the concavity of in the direction of y; the second last inequality is a use of (34) and the Young's inequality; the last inequality follows from the Young's inequality and the L-smoothness that leads to

$$\begin{aligned}
&(\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))-\nabla_y f(\overline{x}_{t+1},\mathbf{y}_t(i)))^\top(\mathbf{y}'_{t+1}(i)-\mathbf{y}_t(i))\\
\leq&\frac{1}{4\eta}\|\mathbf{y}'_{t+1}(i)-\mathbf{y}_t(i)\|^2+\eta\|\nabla_y f(\overline{x}_{t+1},\mathbf{y}_t(i))-\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))\|\\
\leq&\frac{1}{4\eta}\|\mathbf{y}'_{t+1}(i)-\mathbf{y}_t(i)\|^2+\eta L^2\|\overline{x}_{t+1}-\overline{x}_t\|^2\\
=&\frac{\eta}{4}\|\mathbf{v}'_t(i)\|^2+\gamma^2\eta^3L^2\|\overline{u}_t\|^2
\end{aligned}$$

Using the concavity of $f(x,y)$ in variable y as well as the Jensen's inequality, we have

$$\mathbb{E}[-f(\overline{x}_{t+1},\overline{y}'_{t+1})] \tag{37}$$

$$\leq\ \mathbb{E}\left[-f(\overline{x}_t,\overline{y}_t)-\left(\frac{\eta}{4}-\frac{\eta^2L}{2}\right)\frac{1}{m}\sum_{i=1}^m\|\mathbf{v}'_t(i)\|^2+\left(\frac{\gamma^2\eta^2L}{2}+\gamma^2\eta^3L^2+\frac{3\gamma^2\eta}{2}\right)\|\overline{u}_t\|^2\right] \tag{38}$$

$$+\frac{1}{m}\sum_{i=1}^m\mathbb{E}\left[\frac{\eta}{2}\|\nabla_x f(\overline{x}_t,\mathbf{y}_t(i))-\overline{u}_t\|^2+\frac{\eta}{2}\|\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))-\mathbf{v}_t(i))\|^2+\frac{1}{2\eta}\|\overline{y}_t-\mathbf{y}_t(i)\|^2\right] \tag{39}$$

Note that $\overline{y}'_{t+1}=\overline{y}_{t+1}$. Adding (23) multiplying $(1+\alpha)$ along with (37) multiplying α, we get

$$\begin{aligned}
&\mathbb{E}[P_{t+1}]\\
\leq&P_t+(1+\alpha)\mathbb{E}\left[-\frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2-\left(\frac{\gamma\eta}{2}-\frac{L_P\gamma^2\eta^2}{2}\right)\|\overline{u}_t\|^2\right]+(1+\alpha)\times\\
&\mathbb{E}\left[\frac{8\kappa^2\gamma\eta}{m}\sum_{i=1}^m\|\mathbf{v}'_t(i)\|^2+\frac{8\kappa^2\gamma\eta}{m}\sum_{i=1}^m\|\mathbf{v}_t(i)-\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))\|^2+\frac{\gamma\eta}{m}\sum_{i=1}^m\|\overline{u}_t-\nabla_x f(\overline{x}_t,\mathbf{y}_t(i))\|^2\right]\\
&+\alpha\left[-\left(\frac{\eta}{4}-\frac{\eta^2L}{2}\right)\frac{1}{m}\sum_{i=1}^m\|\mathbf{v}'_t(i)\|^2+\left(\frac{\gamma^2\eta^2L}{2}+\gamma^2\eta^3L^2+\frac{3\gamma^2\eta}{2}\right)\|\overline{u}_t\|^2\right]\\
&+\frac{\alpha}{m}\sum_{i=1}^m\mathbb{E}\left[\frac{\eta}{2}\|\nabla_x f(\overline{x}_t,\mathbf{y}_t(i))-\overline{u}_t\|^2+\frac{\eta}{2}\|\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))-\mathbf{v}_t(i))\|^2+\frac{1}{2\eta}\|\overline{y}_t-\mathbf{y}_t(i)\|^2\right]
\end{aligned}$$

Rearranging the above result leads to

$$\begin{aligned}
\mathbb{E}[\Psi_{t+1}]\leq&\mathbb{E}\left[\Psi_t-\frac{(1+\alpha)\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2\right]\\
&-\left((1+\alpha)\left(\frac{\gamma\eta}{2}-\frac{L_P\gamma^2\eta^2}{2}\right)-\alpha\left(\frac{L\gamma^2\eta^2}{2}+\gamma^2\eta^3L+\frac{3\gamma^2\eta}{2}\right)\right)\mathbb{E}[\|\overline{u}_t\|^2]\\
&-\left(\alpha\left(\frac{\eta}{4}-\frac{L\eta^2}{2}\right)-(1+\alpha)8\kappa^2\gamma\eta\right)\frac{1}{m}\sum_{i=1}^m\mathbb{E}[\|\mathbf{v}'_t(i)\|^2]
\end{aligned}$$

$$+\left((1+\alpha)\gamma+\frac{\alpha}{2}\right)\frac{\eta}{m}\sum_{i=1}^{m}\mathbb{E}[\|\overline{u}_t-\nabla_x f(\overline{x}_t,\mathbf{y}_t(i))\|^2]$$
$$+\left((1+\alpha)8\kappa^2\gamma+\frac{\alpha}{2}\right)\frac{\eta}{m}\sum_{i=1}^{m}\mathbb{E}[\|\mathbf{v}_t(i)-\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))\|^2]$$
$$+\frac{\alpha}{2\eta m}\sum_{i=1}^{m}\mathbb{E}[\|\overline{y}_t-\mathbf{y}_t(i)\|^2]$$

Since $\alpha\in(0,1]$, taking $\eta\le 1/(4L)$ and the definition of γ in (9) mean

$$\alpha\left(\frac{\eta}{4}-\frac{L\eta^2}{2}\right)-(1+\alpha)8\kappa^2\gamma\eta\ge\frac{\alpha\eta}{16}$$

as well as

$$(1+\alpha)\left(\frac{\gamma\eta}{2}-\frac{L_P\gamma^2\eta^2}{2}\right)-\alpha\left(\frac{L\gamma^2\eta^2}{2}+\gamma^2\eta^3L+\frac{3\gamma^2\eta}{2}\right)\ge\frac{\gamma\eta}{4}$$

Also, the fact $\alpha\in(0,1]$ and our choice of γ means

$$8(1+\alpha)\kappa^2\gamma+\frac{\alpha}{2}\le\alpha\qquad\text{and}\qquad(1+\alpha)8\kappa^2\gamma+\frac{\alpha}{2}\le\alpha$$

Therefore, we obtain the optimization bound as

$$\mathbb{E}[\Psi_{t+1}]\le\mathbb{E}\left[\Psi_t-\frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2-\frac{\gamma\eta}{4}\|\overline{u}_t\|^2-\frac{\alpha\eta}{16m}\sum_{i=1}^{m}\|\mathbf{v}_t'(i)\|^2\right] \tag{40}$$
$$+\mathbb{E}\left[\frac{\alpha\eta}{m}\sum_{i=1}^{m}\|\overline{u}_t-\nabla_x f(\overline{x}_t,\mathbf{y}_t(i)\|^2+\frac{\alpha\eta}{m}\sum_{i=1}^{m}\|\mathbf{v}_t(i)-\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))\|^2+\frac{\alpha}{2\eta m}\sum_{i=1}^{m}\|\overline{y}_t-\mathbf{y}_t(i)\|^2\right] \tag{41}$$

Note that it holds that

$$\sum_{i=1}^{m}\|\mathbf{v}_t(i)-\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))\|^2\le 3m\|\overline{v}_t-\nabla_y f(\overline{x}_t,\overline{y}_t)\|^2+3\|\mathbf{v}_t-\mathbf{1}\overline{v}_t\|^2+3L^2\|\mathbf{y}_t-\mathbf{1}\overline{y}_t\|^2$$

and

$$\sum_{i=1}^{m}\|\overline{u}_k-\nabla_x f(\overline{x}_t,\mathbf{y}_t(i))\|^2\le 2m\|\overline{u}_t-\nabla_x f(\overline{x}_t,\overline{y}_t)\|^2+2L^2\|\mathbf{y}_t-\mathbf{1}\overline{y}_t\|^2$$

where we use the L-smoothness and Young's inequality. Then we combine Lemma A.5 to get

$$\frac{\alpha\eta}{m}\sum_{i=1}^{m}\|\overline{u}_t-\nabla_x f(\overline{x}_t,\mathbf{y}_t(i)\|^2+\frac{\alpha\eta}{m}\sum_{i=1}^{m}\|\mathbf{v}_t(i)-\nabla_y f(\overline{x}_t,\mathbf{y}_t(i))\|^2 \tag{42}$$
$$\le\frac{6\alpha\eta L^2}{m}\|\mathbf{y}_t-\mathbf{1}\overline{y}_t\|^2+\frac{3\alpha\eta}{m}\|\overline{s}_t-\nabla f(\overline{x}_t,\overline{y}_t)\|^2+\frac{3\alpha\eta}{m}\|\mathbf{v}_t-\mathbf{1}\overline{v}_t\|^2 \tag{43}$$
$$\le\frac{\alpha}{2\eta m}\|\mathbf{y}_t-\mathbf{1}\overline{y}_t\|^2+3\alpha\eta\|\overline{s}_t-\nabla f(\overline{x}_t,\overline{y}_t)\|^2+\frac{3\alpha\eta}{m}\|\mathbf{v}_t-\mathbf{1}\overline{v}_t\|^2 \tag{44}$$

where we use $\eta \leq 1/(4L)$. Plugging (42) into (40) and then use the inequality

$$\frac{1}{m}\sum_{i=1}^{m}\|\mathbf{v}_t'(i)\|^2 \geq \|\overline{v}_t'\|^2$$

Hence, we have

$$\begin{aligned}\mathbb{E}[\Psi_{t+1}] \leq \mathbb{E}\left[\Psi_t - \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \frac{\gamma\eta}{4}\|\overline{u}_t\|^2 - \frac{\alpha\eta}{16}\|\overline{v}_t'\|^2\right] \\ + \mathbb{E}\left[3\alpha\eta\|\overline{s}_t - \nabla_x f(\overline{x}_t, \overline{y}_t)\|^2 + \frac{3\alpha\eta}{m}\|\mathbf{v}_t - \mathbf{1}\overline{v}_t\|^2 + \frac{\alpha}{\eta m}\|\mathbf{y}_t - \overline{y}_t\|^2\right]\end{aligned}$$

Combining with Lemma A.5 and using $\|\mathbf{y}_t - \mathbf{1}\overline{y}_t\| \leq \|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|$ and $\eta \leq 1/(4L)$, we obtain

$$\begin{aligned}\mathbb{E}[\Psi_{t+1}] \leq \mathbb{E}\left[\Psi_t - \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \frac{\gamma\eta}{4}\|\overline{u}_t\|^2 - \frac{\alpha\eta}{16}\|\overline{v}_t'\|^2\right] \\ + \mathbb{E}\left[\frac{3\alpha\eta}{m}\|\mathbf{v}_t - \mathbf{1}\overline{v}_t\|^2 + 6\alpha\eta\left\|\frac{1}{m}\sum_{i=1}^{m}(\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i)))\right\|^2 + \frac{2\alpha}{\eta m}\|\mathbf{z}_t - \overline{z}_t\|^2\right]\end{aligned}$$

Note that

$$\overline{u}_t = \frac{\overline{x}_t - \overline{x}_{t+1}}{\gamma\eta}, \quad \overline{v}_t' = \frac{\overline{y}_{t+1} - \overline{y}_t}{\eta} \quad \text{and} \quad \frac{1}{8\gamma\eta} \geq \frac{\alpha}{16\eta}$$

then we have

$$\begin{aligned}\mathbb{E}[\Psi_{t+1}] \leq \mathbb{E}\left[\Psi_t - \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \frac{1}{8\gamma\eta}\|\overline{x}_{t+1} - \overline{x}_t\|^2 - \frac{\alpha}{16\eta}\|\overline{z}_{t+1} - \overline{z}_t\|^2\right] \\ + \mathbb{E}\left[\frac{3\alpha\eta}{m}\|\mathbf{v}_t - \mathbf{1}\overline{v}_t\|^2 + 6\alpha\eta\left\|\frac{1}{m}\sum_{i=1}^{m}(\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i)))\right\|^2 + \frac{2\alpha}{\eta m}\|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2\right]\end{aligned}$$

Recalling the definition of C_t and U_t, we obtain the result of Lemma 3.1. □

D The Proof of Lemma 3.2

Proof. The relation of (22) means

$$\begin{aligned}&\|\mathbf{x}_{t+1} - \mathbf{1}\overline{x}_{t+1}\| \\ =&\rho\,\|\mathbf{x}_t - \gamma\eta\mathbf{u}_t - \mathbf{1}(\overline{x}_t - \eta\overline{u}_t)\| \\ \leq&\rho\,(\|\mathbf{x}_t - \mathbf{1}\overline{x}_t\| + \gamma\eta\,\|\mathbf{u}_t - \mathbf{1}\overline{u}_t\|)\end{aligned}$$

where the last step is due to triangle inequality. Similarly, we define the notation $\overline{\Pi}(\cdot) = \frac{1}{m}\mathbf{1}\mathbf{1}^\top(\cdot)$ for convenience. Then for variable y, we can verify that

$$\begin{aligned}&\left\|\mathbf{y}_{t+1} - \mathbf{1}\overline{y}_{t+1}\right\| \\ \leq&\rho\left\|\Pi(\mathbf{y}_t + \eta\mathbf{v}_t) - \frac{1}{m}\mathbf{1}\mathbf{1}^\top\Pi\left(\mathbf{y}_t + \eta\mathbf{v}_t\right)\right\| \\ \leq&\rho\,\|\Pi(\mathbf{y}_t + \eta\mathbf{v}_t) - \Pi(\mathbf{1}\overline{y}_t + \eta\mathbf{1}\overline{v}_t)\| + \rho\left\|\Pi(\mathbf{1}\overline{y}_t + \eta\mathbf{1}\overline{v}_t) - \mathbf{1}\overline{\Pi}\left(\mathbf{y}_t + \eta\mathbf{v}_t\right)\right\|\end{aligned}$$

$$
\begin{aligned}
&\leq 2\rho \left\| \mathbf{y}_t + \eta \mathbf{v}_t - \mathbf{1}(\overline{y}_t + \eta \overline{v}_t) \right\| \\
&\leq 2\rho \left(\left\| \mathbf{y}_t - \mathbf{1}\overline{y}_t \right\| + \eta \left\| \mathbf{v}_t - \mathbf{1}\overline{v}_t \right\| \right)
\end{aligned}
$$

where in the third inequality we use the non-expansiveness of projection and Lemma 11 in [YZLZ20], i.e.

$$
\left\| \mathbf{1}\overline{\Pi}(\mathbf{x}) - \Pi(\mathbf{1}\overline{x}) \right\| \leq \left\| \mathbf{x} - \mathbf{1}\overline{x} \right\|
$$

Consequently, we use Young's inequality together with $\gamma \in (0, 1]$ to obtain

$$
\begin{aligned}
&\left\| \mathbf{z}_{t+1} - \mathbf{1}\overline{z}_{t+1} \right\|^2 && (45) \\
&= \left\| \mathbf{x}_{t+1} - \mathbf{1}\overline{x}_{t+1} \right\|^2 + \left\| \mathbf{y}_{t+1} - \mathbf{1}\overline{y}_{t+1} \right\|^2 && (46) \\
&\leq 8\rho^2 \left\| \mathbf{y}_t - \mathbf{1}\overline{y}_t \right\|^2 + 8\rho^2\eta^2 \left\| \mathbf{v}_t - \mathbf{1}\overline{v}_t \right\|^2 + 2\rho^2 \left\| \mathbf{x}_t - \mathbf{1}\overline{x}_t \right\|^2 + 2\rho^2\eta^2 \left\| \mathbf{y}_t - \mathbf{1}\overline{y}_t \right\|^2 && (47) \\
&\leq 8\rho^2 \left\| \mathbf{z}_t - \mathbf{1}\overline{z}_t \right\|^2 + 8\rho^2\eta^2 \left\| \mathbf{s}_t - \mathbf{1}\overline{s}_t \right\|^2 && (48)
\end{aligned}
$$

Furthermore, if $24\rho^2 \leq 1$, we have

$$
\begin{aligned}
&\left\| \mathbf{z}_{t+1} - \mathbf{z}_t \right\|^2 && (49) \\
&\leq 3\|\mathbf{z}_{t+1} - \mathbf{1}\overline{z}_{t+1}\|^2 + 3\|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2 + 3\|\mathbf{1}\overline{z}_t - \mathbf{1}\overline{z}_{t+1}\|^2 && (50) \\
&\leq (24\rho^2 + 3)\|\mathbf{z}_t - \mathbf{1}\overline{z}_k\|^2 + 24\rho^2\eta^2\|\mathbf{s}_t - \mathbf{1}\overline{s}_t\|^2 + 3\|\mathbf{1}\overline{z}_t - \mathbf{1}\overline{z}_{t+1}\|^2 && (51) \\
&\leq 4\|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2 + \eta^2\|\mathbf{s}_t - \mathbf{1}\overline{s}_t\|^2 + 3m\|\overline{z}_t - \overline{z}_{t+1}\|^2 && (52)
\end{aligned}
$$

We let $\rho_t = \rho'$ for $\zeta_t = 1$ and $\rho_t = \rho$ otherwise. The update of $\mathbf{g}_{t+1}(i)$ means

$$
\begin{aligned}
&\mathbb{E}\left[\rho_t^2 \left\| \mathbf{g}_{t+1}(i) - \mathbf{g}_t(i) \right\|^2\right] \\
=&\rho'^2 p \mathbb{E} \left\| \frac{1}{b'} \sum_{\xi_{i,j} \in \mathcal{S}_t'(i)} \nabla F_i(\mathbf{z}_{t+1}(i); \xi_{i,j}) - \mathbf{g}_t(i) \right\|^2 + \frac{\rho^2(1-p)}{bq} \mathbb{E} \left\| \nabla F_i(\mathbf{z}_{t+1}(i); \xi_{i,1}) - \nabla F_i(\mathbf{z}_t(i); \xi_{i,1}) \right\|^2 \\
\leq& 3\rho'^2 p \mathbb{E} \left\| \frac{1}{b'} \sum_{\xi_{i,j} \in \mathcal{S}_t'(i)} \nabla F_i(\mathbf{z}_{t+1}(i); \xi_{i,j}) - \nabla f_i(\mathbf{z}_{t+1}(i)) \right\|^2 + 3\rho'^2 p \mathbb{E} \left\| \nabla f_i(\mathbf{z}_{t+1}(i)) - \nabla f_i(\mathbf{z}_t(i)) \right\|^2 \\
&+ 3\rho'^2 p \mathbb{E} \left\| \nabla f_i(\mathbf{z}_t(i)) - \mathbf{g}_t(i) \right\|^2 + \frac{\rho^2(1-p)L^2}{bq} \mathbb{E} \left\| \mathbf{z}_{t+1}(i) - \mathbf{z}_t(i) \right\|^2 \\
\leq& \frac{3\rho'^2 p \sigma^2}{b'} \mathbb{I}[b' < n] + 3\rho'^2 p L^2 \mathbb{E} \left\| \mathbf{z}_{t+1}(i) - \mathbf{z}_t(i) \right\|^2 \\
&+ 3\rho'^2 p \mathbb{E} \left\| \nabla f_i(\mathbf{z}_t(i)) - \mathbf{g}_t(i) \right\|^2 + \frac{\rho^2(1-p)L^2}{bq} \mathbb{E} \left\| \mathbf{z}_{t+1}(i) - \mathbf{z}_t(i) \right\|^2 \\
\leq& \frac{3\rho'^2 p \sigma^2}{b'} \mathbb{I}[b' < n] + 3\rho'^2 p \mathbb{E} \left\| \nabla f_i(\mathbf{z}_t(i)) - \mathbf{g}_t(i) \right\|^2 + \left(\frac{1-p}{bq} + 3p \right) \rho^2 L^2 \mathbb{E} \left\| \mathbf{z}_{t+1}(i) - \mathbf{z}_t(i) \right\|^2
\end{aligned}
$$

where the first inequality is based on update rules and Assumption 2.4; the second inequality is based on triangle inequality and the last inequality is due to Assumption 2.2. Summing over above result over $i = 1, \ldots, m$, obtain

$$
\mathbb{E}\left[\rho_t^2 \left\| \mathbf{g}_{t+1} - \mathbf{g}_t \right\|^2\right] \leq \frac{3\rho'^2 m p \sigma^2}{b'} \mathbb{I}[b' < n] + 3\rho'^2 p \mathbb{E} \left\| \nabla \mathbf{f}(\mathbf{z}_t) - \mathbf{g}_t \right\|^2 + \left(\frac{1-p}{bq} + 3p \right) \rho^2 L^2 \mathbb{E} \left\| \mathbf{z}_{t+1} - \mathbf{z}_t \right\|^2
$$

Let $c = \max\{1/(bq), 1\}$ and plug it into (49), then

$$\begin{aligned}
&\mathbb{E}[\rho_t^2 \|\mathbf{g}_{t+1} - \mathbf{g}_t\|^2] && (53)\\
\leq &\frac{3\rho'^2 m\sigma^2}{b'}\mathbb{I}[b' < n] + 3\rho'^2\mathbb{E}[\|\nabla \mathbf{f}(\mathbf{z}_t) - \mathbf{g}_t\|^2] + c\rho^2 L^2 \mathbb{E}[\|\mathbf{z}_{t+1} - \mathbf{z}_t\|^2] && (54)\\
\leq &\frac{3\rho'^2 m\sigma^2}{b'}\mathbb{I}[b' < n] + 3\rho'^2\mathbb{E}[\|\nabla \mathbf{f}(\mathbf{z}_t) - \mathbf{g}_t\|^2] && (55)\\
&+ 16c\rho^2 L^2 \mathbb{E}[\|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2] + 4c\rho^2 L^2\eta^2\mathbb{E}[\|\mathbf{s}_t - \mathbf{1}\overline{s}_t\|^2] + 12c\rho^2 m L^2 \mathbb{E}[\|\overline{z}_{t+1} - \overline{z}_t\|^2] && (56)
\end{aligned}$$

Furthermore, we have

$$\begin{aligned}
&\|\mathbf{s}_{t+1} - \mathbf{1}\overline{s}_{t+1}\| && (57)\\
\leq &\rho_t \left\|\mathbf{s}_t + \mathbf{g}_{t+1} - \mathbf{g}_t - \frac{1}{m}\mathbf{1}\mathbf{1}^\top(\mathbf{s}_t + \mathbf{g}_{t+1} - \mathbf{g}_t)\right\| && (58)\\
\leq &\rho_t \|\mathbf{s}_t - \mathbf{1}\overline{s}_t\| + \rho_t \left\|\mathbf{g}_{t+1} - \mathbf{g}_t - \frac{1}{m}\mathbf{1}\mathbf{1}^\top(\mathbf{g}_{t+1} - \mathbf{g}_t)\right\| && (59)\\
\leq &\rho_t \|\mathbf{s}_t - \mathbf{1}\overline{s}_t\| + \rho_t \|\mathbf{g}_{t+1} - \mathbf{g}_t\| && (60)
\end{aligned}$$

where the second inequality is based on triangle inequality and the last step uses Lemma A.2. Combining the results of (53) and (57) and using $\eta \leq 1/(4L)$, we have

$$\begin{aligned}
&\eta^2\mathbb{E}\|\mathbf{s}_{t+1} - \mathbf{1}\overline{s}_{t+1}\|^2 && (61)\\
\leq &2\rho^2\eta^2\|\mathbf{s}_t - \mathbf{1}\overline{s}_t\|^2 + 2\eta^2\mathbb{E}[\rho_t^2\|\mathbf{g}_{t+1} - \mathbf{g}_t\|^2] && (62)\\
\leq &4c\rho^2\eta^2\mathbb{E}[\|\mathbf{s}_t - \mathbf{1}\overline{s}_t\|^2] + 4c\rho^2\mathbb{E}[\|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2] && (63)\\
&+ 6\rho'^2\eta^2\mathbb{E}[\|\nabla\mathbf{f}(\mathbf{z}_t) - \mathbf{g}_t\|^2] + 2c\rho^2 m\mathbb{E}[\|\overline{z}_{t+1} - \overline{z}_t\|^2] + \frac{6\rho'^2 m\eta^2\sigma^2}{b'}\mathbb{I}[b' < n] && (64)
\end{aligned}$$

Combining (61) and (45), we obtain

$$\begin{aligned}
&\mathbb{E}\big[\|\mathbf{z}_{t+1} - \mathbf{1}\overline{z}_{t+1}\|^2 + \eta^2\|\mathbf{s}_{t+1} - \mathbf{1}\overline{s}_{t+1}\|^2\big]\\
\leq &12c\rho^2\mathbb{E}[\|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2 + \eta^2\|\mathbf{s}_t - \mathbf{1}\overline{s}_t\|^2] + 6\rho'^2\eta^2\mathbb{E}[\|\nabla\mathbf{f}(\mathbf{z}_t) - \mathbf{g}_t\|^2] + 2c\rho^2 m\mathbb{E}[\|\overline{z}_{t+1} - \overline{z}_t\|^2] + \frac{6\rho'^2 m\eta^2\sigma^2}{b'}\mathbb{I}[b' < n]
\end{aligned}$$

which finishes our proof. □

E The Proof of Lemma 3.3

Proof. The update of $\mathbf{g}_{t+1}(i)$ means

$$\begin{aligned}
&\mathbb{E}\|\mathbf{g}_{t+1}(i) - \nabla f_i(\mathbf{z}_{t+1}(i))\|^2\\
=&p\mathbb{E}\left\|\frac{1}{b'}\sum_{\xi_{i,j}\in\mathcal{S}_t'(i)}\nabla F_i(\mathbf{z}_{t+1}(i);\xi_{i,j}) - \nabla f_i(\mathbf{z}_{t+1}(i))\right\|^2\\
&+ (1-p)\mathbb{E}\left\|\mathbf{g}_t(i) + \frac{\omega_t(i)}{bq}\sum_{\xi_{i,j}\in\mathcal{S}_t(i)}\big(\nabla F_i(\mathbf{z}_{t+1}(i);\xi_{i,j}) - \nabla F_i(\mathbf{z}_t(i);\xi_{i,j})\big) - \nabla f_i(\mathbf{z}_{t+1}(i))\right\|^2
\end{aligned}$$

$$
\begin{aligned}
\leq & \frac{p\sigma^2}{b'}\mathbb{I}[b'<n] + (1-p)\mathbb{E}\Big\|\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i)) \\
& + \frac{\omega_t(i)}{bq}\sum_{\xi_{i,j}\in\mathcal{S}_t(i)}\big(\nabla F_i(\mathbf{z}_{t+1}(i);\xi_{i,j}) - \nabla F_i(\mathbf{z}_t(i);\xi_{i,j}) - \nabla f_i(\mathbf{z}_{t+1}(i)) + \nabla f_i(\mathbf{z}_t(i))\big)\Big\|^2 \\
= & \frac{p\sigma^2}{b'}\mathbb{I}[b'<n] + (1-p)\mathbb{E}\left\|\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i))\right\|^2 \\
& + (1-p)\mathbb{E}\left\|\frac{\omega_t(i)}{bq}\sum_{\xi_{i,j}\in\mathcal{S}_t(i)}\big(\nabla F_i(\mathbf{z}_{t+1}(i);\xi_{i,j}) - \nabla F_i(\mathbf{z}_t(i);\xi_{i,j}) - \nabla f_i(\mathbf{z}_{t+1}(i)) + \nabla f_i(\mathbf{z}_t(i))\big)\right\|^2 \\
\leq & \frac{p\sigma^2}{b'}\mathbb{I}[b'<n] + (1-p)\mathbb{E}\left\|\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i))\right\|^2 + \frac{1-p}{bq}\mathbb{E}\left\|\nabla F_i(\mathbf{z}_{t+1}(i);\xi_{i,j}) - \nabla F_i(\mathbf{z}_t(i);\xi_{i,j})\right\|^2 \\
\leq & \frac{p\sigma^2}{b'}\mathbb{I}[b'<n] + (1-p)\mathbb{E}\left\|\mathbf{g}_t(i) - \nabla f_i(\mathbf{z}_t(i))\right\|^2 + \frac{(1-p)L^2}{bq}\mathbb{E}\left\|\mathbf{z}_{t+1}(i) - \mathbf{z}_t(i)\right\|^2
\end{aligned}
$$

where the first inequality is based on Assumption 2.4; the second inequality use the property of variance; the last inequality is based on Assumption 2.2; the second equality uses the property of martingale according to Proposition 1 in [FLLZ18]. Taking the average over $i = 1, \ldots, m$ for above result and using (49), we obtain

$$
\begin{aligned}
& \mathbb{E}\left\|\mathbf{g}_{t+1} - \nabla\mathbf{f}(\mathbf{z}_{t+1})\right\|^2 && (65)\\
\leq & \frac{mp\sigma^2}{b'}\mathbb{I}[b'<n] + (1-p)\mathbb{E}\left\|\mathbf{g}_t - \nabla\mathbf{f}(\mathbf{z}_t)\right\|^2 + \frac{(1-p)L^2}{bq}\mathbb{E}\left\|\mathbf{z}_{t+1} - \mathbf{z}_t\right\|^2 && (66)\\
\leq & \frac{mp\sigma^2}{b'}\mathbb{I}[b'<n] + (1-p)\mathbb{E}\left\|\mathbf{g}_t - \nabla\mathbf{f}(\mathbf{z}_t)\right\|^2 && (67)\\
& + \frac{(1-p)L^2}{bq}\mathbb{E}[4\|\mathbf{z}_t - \mathbf{1}\overline{z}_t\|^2 + \eta^2\|\mathbf{s}_t - \mathbf{1}\overline{s}_t\|^2 + 3m\|\overline{z}_{t+1} - \overline{z}_t\|^2] && (68)
\end{aligned}
$$

which is the variance bound as claimed by the definition of V_t. □

F The Proof of Lemma 3.4

We omit the detailed proof since it is almost identical to the proof of Lemma 3.3. We leave this as an exercise to the reader. Compared with Lemma 3.3, the quantities in Lemma 3.4 can be scaled with an additional factor of $1/m$ by using the fact

$$
\mathbb{E}\Big\|\sum_{i=1}^m a_i\Big\|^2 = \sum_{i=1}^m \mathbb{E}\|a_i\|^2
$$

where each $a_1, \ldots, a_m$ are independent with zero mean.

G The Proof of Theorem 3.1

Proof. Combing Lemma 3.1, 3.2, 3.3 and 3.4 together, we obtain

$$
\mathbb{E}[\Phi_{t+1}]
$$

$$
\begin{aligned}
\leq & \mathbb{E}\left[\Phi_t - \frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \frac{1}{8\gamma\eta}\|\overline{x}_{t+1} - \overline{x}_t\|^2 - \frac{\alpha}{16\eta}\|\overline{z}_{t+1} - \overline{z}_t\|^2 + 6\alpha\eta U_t + \frac{3\alpha}{m\eta}C_t\right] \\
& + \frac{\eta}{mp}\mathbb{E}\left[-pV_t + \frac{4(1-p)L^2}{mbq}C_t + \frac{3(1-p)L^2}{bq}\|\overline{z}_{t+1} - \overline{z}_t\|^2 + \frac{p\sigma^2}{b'}\mathbb{I}[b' < n]\right] \\
& + \frac{\eta}{p}\mathbb{E}\left[-pU_t + \frac{4(1-p)L^2}{m^2bq}C_t + \frac{3(1-p)L^2}{mbq}\|\overline{z}_{t+1} - \overline{z}_t\|^2 + \frac{p\sigma^2}{mb'}\mathbb{I}[b' < n]\right] \\
& + \frac{1}{\eta m}\mathbb{E}\left[-(1 - 12c\rho^2)C_t + 6m\rho'^2\eta^2 V_t + 2c\rho^2 m\mathbb{E}[\|\overline{z}_{t+1} - \overline{z}_t\|^2] + \frac{6\rho'^2 m\eta^2\sigma^2}{b'}\mathbb{I}[b' < n]\right] \\
= & \Phi_t + \mathbb{E}\left[-\frac{\gamma\eta}{2}\|\nabla P(\overline{x}_t)\|^2 - \frac{1}{8\gamma\eta}\|\overline{x}_{t+1} - \overline{x}_t\|^2 - \left(\frac{\alpha}{16\eta} - \frac{2c\rho^2}{\eta} - \frac{6\eta(1-p)L^2}{mbpq}\right)\|\overline{z}_{t+1} - \overline{z}_t\|^2\right] \\
& - (1 - 6\alpha)\eta U_t - \frac{(1 - 6m\rho'^2)\eta}{m}V_t - \left(\frac{1 - 12c\rho^2 - 3\alpha}{\eta m} - \frac{8(1-p)L^2}{m^2bpq}\right)C_t \\
& \quad + \left(6\rho'^2\frac{2}{m}\right)\frac{\eta\sigma^2}{b'}\mathbb{I}[b' < n]
\end{aligned}
$$

Plugging in our setting of parameters in (13), it can be seen that

$$
\mathbb{E}[\Phi_{t+1}] \leq \Phi_t - \frac{\gamma\eta}{2}\mathbb{E}[\|\nabla P(\overline{x}_t)\|^2] - \frac{4\alpha}{\eta m}C_t + \frac{3\eta\sigma^2}{mb'}\mathbb{I}[b' < n]
$$

Telescoping for $t = 0, 1 \cdots, T-1$, we obtain

$$
\frac{1}{T}\sum_{t=0}^{T-1}\mathbb{E}[\|\nabla P(\overline{x}_t)\|^2] \leq \frac{2}{\gamma\eta T}\Phi_0 - \frac{8\alpha}{\gamma\eta^2 mT}\sum_{t=0}^{T-1}C_t + \frac{6\sigma^2}{\gamma mb'}\mathbb{I}[b' < n] \tag{69}
$$

Note that achieving $\overline{x}_t$ is not simple, so the output x_{out} is sampled from $\{\mathbf{x}_t(i)\}$ where $t = 0, \ldots, T-1$ and $i = 1, \ldots, m$. We also has the following bound:

$$
\begin{aligned}
\mathbb{E}\,\|\nabla P(x_{\text{out}})\|^2 = & \frac{1}{mT}\sum_{i=1}^{m}\sum_{t=0}^{T-1}\|\nabla P(\mathbf{x}_t(i))\|^2 \\
\leq & \frac{2}{mT}\sum_{i=1}^{m}\sum_{t=0}^{T-1}\left(\|\nabla P(\overline{x}_t)\|^2 + \|\nabla P(\mathbf{x}_t(i)) - \nabla P(\overline{x}_t)\|^2\right) \\
\leq & \frac{2}{mT}\sum_{i=1}^{m}\sum_{t=0}^{T-1}\left(\|\nabla P(\overline{x}_t)\|^2 + L^2\|\mathbf{x}_t(i) - \overline{x}_t\|^2\right) \\
= & \frac{2}{T}\sum_{t=0}^{T-1}\|\nabla P(\overline{x}_t)\|^2 + \frac{2L^2}{mT}\sum_{t=0}^{T-1}\|\mathbf{x}_t - \mathbf{1}\overline{x}_t\|^2 \\
\leq & \frac{2}{T}\sum_{t=0}^{T-1}\|\nabla P(\overline{x}_t)\|^2 + \frac{2L^2}{mT}\sum_{t=0}^{T-1}C_t
\end{aligned}
$$

where the first step use Young's inequality; the second inequality is due to Assumption 2.2. Now we plug in (69) to get the following bound as

$$
\mathbb{E}\|\nabla P(x_{\text{out}})\|^2 \leq \frac{4}{\gamma\eta T}\Phi_0 - \left(\frac{16\alpha}{\gamma\eta^2} - 2L^2\right)\frac{1}{mT}\sum_{t=0}^{T-1}C_t + \frac{12\sigma^2}{\gamma mb'}\mathbb{I}[b' < n]
$$

Recall the choice of γ in (9); $\eta \le 1/(4L)$ and $pT \ge 2$. Hence, we have

$$\begin{aligned}
\mathbb{E}\|\nabla P(x_{\text{out}})\|^2 &\le \frac{4}{\gamma\eta T}\Phi_0 + \frac{12\sigma^2}{\gamma m b'}\mathbb{I}[b' < n] \\
&= \frac{4}{\gamma\eta T}\left(\Psi_0 + \frac{\eta}{mp}V_0 + \frac{\eta}{p}U_0 + \frac{\eta}{m}C_0\right) + \frac{12\sigma^2}{\gamma m b'}\mathbb{I}[b' < n] \\
&= \frac{4}{\gamma\eta T}\left(\Psi_0 + \frac{2\eta\sigma^2}{mb'p}\mathbb{I}[b' < n] + \frac{\eta}{m}\|\mathbf{s}_0 - \mathbf{1}\bar{s}_0\|^2\right) + \frac{12\sigma^2}{\gamma m b'}\mathbb{I}[b' < n] \\
&\le \frac{4}{\gamma\eta T}\left(\Psi_0 + \frac{2\eta\sigma^2}{mb'p}\mathbb{I}[b' < n] + \frac{\eta\rho_0^2}{m}\|\mathbf{g}_0 - \mathbf{1}\bar{g}_0\|^2\right) + \frac{12\sigma^2}{\gamma m b'}\mathbb{I}[b' < n] \\
&\le \frac{8}{\gamma\eta T}\Psi_0 + \frac{16\sigma^2}{\gamma m b'}\mathbb{I}[b' < n] + \frac{4\rho_0^2\|\mathbf{g}_0 - \mathbf{1}\bar{g}_0\|^2}{\gamma m}
\end{aligned}$$

Therefore the parameters in (13) and (16) guarantee that $\mathbb{E}\|\nabla P(x_{\text{out}})\|^2 \le \epsilon^2$. The Jensen's inequality further implies that the output is a nearly stationary point satisfying $\mathbb{E}\|\nabla P(x_{\text{out}})\| \le \epsilon$.

Recall our choice of γ in (9), we know that $1/\gamma = \Theta(\kappa^2)$. Then the total SFO complexity for all agents in expectation is

$$mb' + mT(b'p + bq(1-p)) = mb' + \frac{2mTb'bq}{b' + bq} \le mb' + 2mTbq$$

Plug in the choice of b, b', q yields the SFO complexity as claimed. Next, recalling the definition of ρ, ρ', ρ_0 in (10), we know the total number of communication rounds is

$$K_0 + T(pK' + (1-p)K) = \begin{cases} \mathcal{O}\left(\kappa^2 L\epsilon^{-2}/\sqrt{\delta}\right), & b' \ge m \\ \mathcal{O}\left(\kappa^2 L\epsilon^{-2}\log(m/b')/\sqrt{\delta}\right), & b' < m \end{cases}$$

□
